**Abstract** An annotated checklist of marine and freshwater fishes of Tokunoshima island in the Amami Islands, Kagoshima Prefecture, southern Japan, was compiled from specimen and literature surveys. A total of 505 species (257 genera, 88 families and 19 orders), including 214 species that represent the first reliable records from the island on the basis of collected specimens and/or underwater photographs, are listed with citation of literature, registration numbers, sizes, localities on the island, and some remarks. Preliminary comparisons of the ichthyofauna of the island with those of 14 other localities in Japan show that the fish fauna of Tokunoshima island is similar to that of Yoronjima island in the Amami Islands.

Mochida, I. and H. Motomura. 2018. An annotated checklist of marine and freshwater fishes of Tokunoshima island in the Amami Islands, Kagoshima, southern Japan, with 214 new records. Bulletin of the Kagoshima University Museum, 10: 1–80.

## Introduction

Tokunoshima, a gourd-shaped island, with an area of ca. 248 m<sup>2</sup> and a highest point of 645 m above sea level, is the second largest island in the Amami Islands, which is located at the middle of the Ryukyu Archipelago, southern Japan (Fig. 1). The coastline stretches about 80 km, with well-developed rocky reefs, and there are numerous limestone caves and a large anchialine cave on the island.

Since comprehensive ichthyofaunal surveys of Tokunoshima island have not been previously completed, two large-scale Tokunoshima Expeditions were made in September–October 2014 and November 2015 by the Kagoshima University Museum to study the island's ichthyofauna. In addition, the first author previously lived on the island for several years and collected fishes there from 2013 to 2016. About 2,000 specimens of marine and freshwater fishes were collected during the expeditions and the first author's stay on the island. Sixty six unregistered specimens collected from Tokunoshima island in March–May 1965 were found at the Faculty of Fisheries, Kagoshima University, and these were registered in the fish collection of the Kagoshima University Museum and also used in this study.

Examination of the above-mentioned specimens, published literature (plus examination of specimens used in the literature), and unpublished underwater photographs taken in Tokunoshima island confirmed 505 species of marine and freshwater fishes, including 214 new records, from the island. All species are listed below. The ichthyofauna of Tokunoshima island is briefly compared with that of other islands in the Ryukyu, Osumi, and Ogasawara islands, and several localities along the Pacific coast of southern Japan.

## Material and methods

Sampling methods were described and illustrated in Motomura & Matsuura (2010, 2014). Curatorial procedures for newly collected specimens followed Motomura & Ishikawa (2013). Standard and total lengths are abbreviated as SL and TL respectively. The systematic arrangement of families generally follows Nelson (2006). Scientific names generally follow Eschmeyer et al. (2018), with some modifications following recently published or unpublished taxonomic studies. Within families, species are arranged in alphabetical order of the scientific name. Standard Japanese names generally follow Nakabo (2013), having been transliterated using the Hepburn system. Each species record was compiled from voucher specimens, underwater photographs, and/or published literature. Registration number, number of specimens registered (if more than one), mm in SL or TL, and locality on Tokunoshima island (Fig. 2) are listed in each species record. “Tokunoshima island” and “Tokunoshima” are the names of the island and the town respectively. Tokunoshima island has three towns: Tokunoshima (on the east side of the island), Amagi (west side), and Isen (south side). The localities of marine and freshwater fishes are indicated as names of “area, town (e.g., Kaneku, Amagi)” and “river (e.g., Akirigami River)” respectively. The locality is expressed simply as “Tokunoshima island” if the fish(es) were collected far off the island or if the precise locality on the island is unknown.

Institutional codes used in this paper are as follows: FAKU (Kyoto University Museum, Kyoto, Japan), FSKU (School of Fisheries Sciences, Kitasato University, Iwate, Japan), KAUM (Kagoshima University Museum, Kagoshima, Japan), KPM (Kanagawa Prefectural Museum of Natural History, Kanagawa, Japan), LICPP (Laboratory of Ichthyology, the Crown Prince's Palace, Tokyo, Japan), MIKU (Marine Biological Institute of Kyoto University, Wakayama, Japan; specimens currently transferred to FAKU), SMBL (Seto Marine Biology Laboratory, Kyoto University, Wakayama, Japan; specimens currently transferred to FAKU), UPM (Faculty of Science, University of the Ryukyus, Okinawa, Japan; specimens currently transferred to Okinawa Churaumi Aquarium, Okinawa, Japan), and USNM (Museum Support Center of National Museum of Natural History, Smithsonian Institution, Suitland, MD, USA).

## Remarks

The freshwater fishes of Tokunoshima island have been well studied. The oldest available paper related to fishes of the island is probably Kuroiwa (1927) who recorded four species of fishes from rivers on the island:

*Anguilla japonica* Temminck & Schlegel, 1846 and *Anguilla marmorata* Quoy & Gaimard, 1824 (family Anguidae), *Carassius* sp. (as *Carassius auratus*) (family Cyprinidae), and *Misgurnus anguillicaudatus* (Cantor, 1842) (family Cobitidae). *Misgurnus anguillicaudatus* is currently rare on the island (Kano et al., 2016) and is probably in danger of extinction from the island.

*Opsariichthys platypus* (Temminck & Schlegel, 1846) (Fig. 3A, B) was probably introduced into the Akirigami River (Fig. 3C) from the Amori River on the mainland of Kagoshima along with *Plecoglossus altivelis altivelis* (Temminck & Schlegel, 1946) in May 1979 (Nishida et al., 1992; Sawashi, 1995, 1997). However, the population of *O. platypus* in the Shikaura River is likely to be established more recently (Sawashi, 1995). Although *O. platypus* is not native to Tokunoshima island, the southern limit of its distributional range in Japan is Tokunoshima island. Incidentally, *P. a. altivelis* has never been observed or recorded from Tokunoshima island since 1979 (Sawashi, 1997).

Marine fishes of the island have been poorly studied. The only known species described as new on the basis of a primary type specimen from Tokunoshima island is *Kaupichthys japonicus* Matsubara & Asano, 1960 (family Chlopsidae). This species is currently known from Tokunoshima and Yoronjima islands (both in the Amami Islands) and southern Taiwan (Hatooka, 2013a; Hibino, 2014a).

There is an anchialine cave (locally called Umbuki) in Amagi, northwestern Tokunoshima island (Fig. 4C). Two species of fishes, *Xenoconger fryeri* Regan, 1912 (family Chlopsidae) (Fig. 4A) and *Eleotris* sp. 1 (family Eleotridae) (Fig. 4B) inhabit the anchialine cave, the former being known only from this anchialine cave on Tokunoshima island in Japan.

The number of species in the top 10 most speciose families occurring at Tokunoshima island are shown in Table 1. Comparable data for 14 localities in southern Japan, including the Sagami Sea, Osezaki (Suruga Bay), Kushimoto (Kii Peninsula), Kashiwajima island (Shikoku), Iwojima and Takeshima islands (Osumi Islands), Yakushima island (Osumi Islands), Amami-oshima island (Amami Islands), Yoronjima island (Amami Islands), Okinawajima island (Okinawa Islands), Iejima island (Okinawa Islands), the Miyako Islands, Ishigakijima island (Yaeyama Islands), Iriomotejima island (Yaeyama Islands), and the Ogasawara Islands, were presented in Motomura (2016: tables 1, 2) and Nakae et al. (2018: table 2). The top three most speciose families in all localities, except for the Sagami Sea, Osezaki (Suruga Bay), and the Ogasawara Islands, are Gobiidae, Pomacentridae and Labridae. The top three most speciose families in the Sagami Sea, Osezaki, and the Ogasawara Islands are Gobiidae, Labridae, and Serranidae (the last family was replaced with Pomacentridae in the other localities) (Motomura, 2016).

Tokunoshima island is geographically located between Amami-oshima and Yoronjima islands. The ichthyofauna of the former is most similar to that of Yoronjima island among the 14 localities in Japan. The top 10 most speciose families, and their percentages of number of species in each family to total number of species in Tokunoshima island are almost the same with those of Yoronjima island (Table 1; Motomura, 2016: table 1). The only difference between Tokunoshima and Yoronjima islands is that the family Monacanthidae ranked as seventh speciose family in Tokunoshima island is not in Yoronjima island and it is replaced with the family Tripterygiidae in Yoronjima island (Motomura, 2016: table 1). High species diversity of Monacanthidae in Tokunoshima island might be caused by the presence of well-developed rocky reefs along the coast of the island where the family members prefer to inhabit.

Table 1. Number of species in the top 10 most speciose families occurring at Tokunoshima island.

Family	No. of species	% in total
Gobiidae	75	14.9
Pomacentridae	38	7.5
Labridae	37	7.3
Blenniidae	23	4.6
Apogonidae	22	4.4
Scorpaenidae	20	4.0

## Acknowledgments

We are especially grateful to R. Suzuki (Marine Service KAMUI, Tokunoshima) for providing underwater photographs and his assistance with collecting fishes in Tokunoshima island, T. Mochida and M. Mochida (Kagoshima) for their devoted support to the first author during this study, students and volunteers of KAUM for providing identifications and their assistance with collecting fishes in the island. We greatly appreciated comments on the manuscript by G. Yearsley (Australia). This study was supported in part by JSPS KAKENHI Grant Numbers JP19770067, JP26241027, JP24370041, JP23580259, and JP26450265; the JSPS Core-to-Core Program: B Asia-Africa Science Platforms; the “Biological Properties of Biodiversity Hotspots in Japan” project of the National Museum of Nature and Science, Tsukuba, Japan; “Establishment of Research and Education Network on Biodiversity and Its Conservation in the Satsunan Islands” project of Kagoshima University adopted by the Ministry of Education, Culture, Sports, Science and Technology, Japan; and the “Island Research” project of Kagoshima University.

## Errata

This page was added on 6 November 2018 after this article was officially published.

The following 12 species of the family Balistidae have mistakenly been placed in the family Monacanthidae in the checklist: *Balistoides conspicillum* (Bloch & Schneider, 1801), *Balistoides viridescens* (Bloch & Schneider, 1801), *Canthidermis maculata* (Bloch, 1786), *Melichthys vidua* (Richardson, 1845), *Odonus niger* (Rüppell, 1836), *Pseudobalistes flavimarginatus* (Rüppell, 1829), *Rhinecanthus aculeatus* (Linnaeus, 1758), *Rhinecanthus rectangulus* (Bloch & Schneider, 1801), *Rhinecanthus verrucosus* (Linnaeus, 1758), *Sufflamen bursa* (Bloch & Schneider, 1801), *Sufflamen chrysopterum* (Bloch & Schneider, 1801), and *Sufflamen fraenatum* (Latreille, 1804). Total numbers of the balistid and monacanthid species occurring off Tokunoshima island are 13 [*Balistapus undulatus* (Park, 1797) has correctly been placed as a member of Balistidae] and 6 respectively.

Based on the correct number of species in Balistidae, the last paragraph of Remarks (page 3) and Table 1 (page 3) are revised as follows: Tokunoshima island is geographically located between Amami-oshima and Yoronjima islands. The ichthyofauna of the former is most similar to that of Yoronjima island among the 14 localities in Japan. The top 10 most speciose families, and their percentages of number of species in each family to total number of species in Tokunoshima island are almost the same with those of Yoronjima island (Table 1; Motomura, 2016: table 1). The major difference between Tokuno-shima and Yoronjima islands is that the family Balistidae ranked as tenth speciose family in Tokunoshima island is not in Yoronjima island and it is replaced with the family Tripterygiidae in Yoronjima island (Motomura, 2016: table 1). High species diversity of Balistidae in Tokunoshima island might be caused by the presence of well-developed rocky reefs along the coast of the island where the family members prefer to inhabit.

Table 1. Number of species in the top 10 most speciose families occurring at Tokunoshima island.

Family	No. of species	% in total
Gobiidae	75	14.9
Pomacentridae	38	7.5
Labridae	37	7.3
Blenniidae	23	4.6
Apogonidae	22	4.4
Scorpaenidae	20	4.0
Serranidae	18	3.6
Chaetodontidae	16	3.2
Acanthuridae	15	3.0
Syngnathidae	13	2.6
Balistidae	13	2.6
Other families	215	42.6
Total	505	100.0

*A total of 505 species, including 214 species that represent the first reliable records from Tokunoshima island on the basis of collected specimens and/or underwater photographs, are listed with citation of literature, registration numbers, sizes, localities on the island, and some remarks.*
